CSC / CPE 357

Systems Programming

UNIX Philosophy

- Make each program do one thing well. To do a new job, build afresh rather than complicate old programs by adding new features.
- Expect the output of every program to become the input to another, as yet unknown, program.

Doug McIlroy, Elliot Pinson and Berk Tague, 1978

The C Programming Language

- Created in 1972 by Dennis Ritchie, evolved alongside UNIX
- "Low-level" language that exposes underlying features of machine architecture
- Procedural, not object-oriented
- Small standard library, compared to Java, Python, C++, etc.

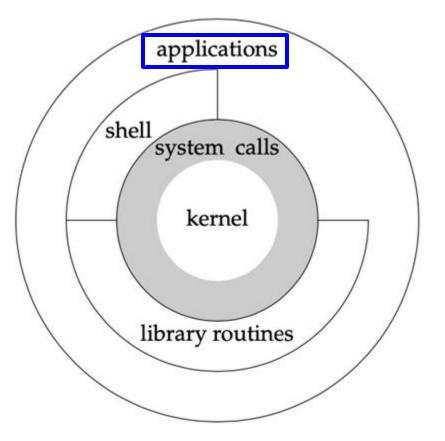

Figure 1.1 Architecture of the UNIX operating system

Diagram from: Advanced Programming in the UNIX Environment, 3rd Ed.

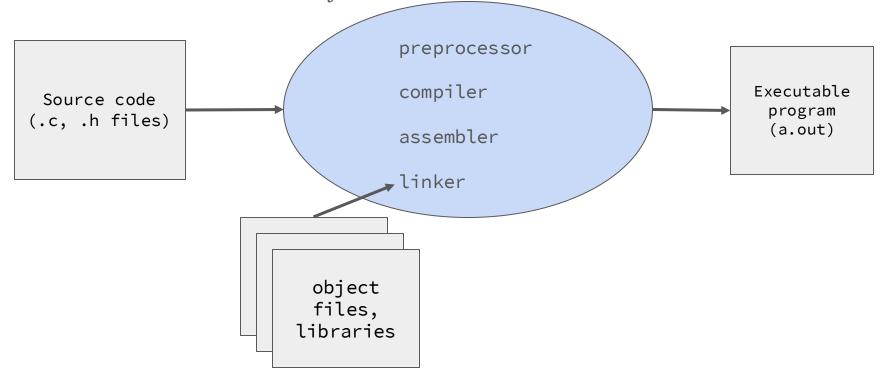

C Filenames

- .c C source file
- .h Header file
 - type definitions, function prototypes and declarations
- .o / a.out Compiled object file

C Compiler / Linker

A **compiler** generates object code files (machine language) from source code.

A **linker** combines these object code files into an executable.

C Program Layout (*.c)

```
#include <system_header.h>
#include "local_header.h"
#define macro_name macro_expr
/* declare functions */
/* declare external variables & structs */
int main(int argc, char* argv[]) {
      /* the code */
/* define other functions */
```

C Data Types

C data types map to typical hardware capabilities:

- **char** a single byte, capable of holding one character (eg. letter)
- **int** an integer, with a size that matches the "natural" size of integers on the host machine (no less than 16 bits)
- **float** single-precision floating point
- **double** double-precision floating point
- **boolean** (no direct support) 0 is false nonzero is true.

Variable Declarations

In C, variables must be declared before use. A **declaration** introduces an identifier and describes its type. A declaration is what the compiler needs to accept references to that identifier. For example:

```
extern int i; // extern indicates that a variable is available elsewhere // resolving is deferred to the linker
```

A **definition** actually instantiates/implements an identifier. It's what the linker needs to link references to those entities:

```
int i = 42;
char upper_a = 'A';
```

A definition can be used without a declaration.

Data Type Qualifiers

The data type qualifier **short** may be applied to integers to provide different lengths of integers where appropriate; **long** may be applied to integers or doubles.

Typically: short intis 16 bits, long intis 32 bits and intis either 16 or 32 bits.

```
short int course_no;
long int counter;
```

The "int" may be omitted. Equivalent declarations:

```
short course_no;
long counter;
```

Data Type Qualifiers

Data type qualifiers control certain behavior. Examples:

• **const** specifies that a variable's value cannot be changed

```
const float pi = 3.14159;
pi = 3.2; // invalid
```

• unsigned holds a value that is always positive or zero

```
unsigned int i; i = -1;
```

Name Description Typical value CHAR_BIT bits in a char

MB_LEN_MAX max number of bytes in a 6	ULLONG_MAX	max value of unsigned	18,446,744,073,709,551,615
		long long	
multibyte character constant	MB_LEN_MAX	max number of bytes in a	6
Trusted to criminate combinate		multibyte character constant	

Data Type Qualifiers (continued)

In addition to qualifiers such as const and unsigned, the following modifiers allow fine-grained control:

- **static** link now
- register store value in a CPU register, if possible
- extern extern declarations (for variables in libraries)
- **volatile** for things that change by themselves
- restrict promises no pointer aliasing

We will return to these as they become relevant.

C Data Structures

- Arrays are contiguous chunks of memory
 - No default initialization of memory content
 - No bounds checking (length not stored)
- C-**strings** are null-terminated arrays of characters
 - \circ char x[] = "hi";
 - string.h has helpful library/utility functions
- Structs are collections of fields (variables)
 - "Object-like" but no methods

The main() Function

int main(int argc, char* argv[])

- **argc** contains the count of arguments on the command line
 - o Executable name counts as one, plus one for each argument
- argv is an array of the arguments as strings
- Example: \$./a.out 14 hi
 - \circ argc = 3
 - o argv[0]="./a.out", argv[1]="14", argv[2]="hi"

Error Handling in C

- No built-in exception handling (no try/catch)
- Errors are returned as integer error codes from functions
 - Error handling is inelegant
 - CONSTANT_NAMES are defined to avoid "magic" integer values need to look up in documentation
- Global variable **errno** holds value of last system error

Error Handling

- Processes exit (e.g., return from main) with status code
- Standard codes found in stdlib.h:
 - EXIT_SUCCESS (usually 0)
 - EXIT_FAILURE (non-zero)
- "Crashes" trigger signals from OS (e.g., SIGSEGV for segfault)

C Functions

- Parameters: all passed by **value**
- Function declarations (prototypes)
 - Specifies function arguments and return type
 - Example: int power(int base, int n);
- Function definitions

Function Declaration vs. Definition

Declaration

- Function prototype, external variable declaration
- Often placed in header files (.h) incorporated via #include
- Should appear before first use in all files that use the function

Definition

- Code for function, or variable definition that creates storage
- Must be exactly one definition of each thing (no duplicates)

Function Declaration vs. Definition

```
// function definition
// power: raise base to n-th power; n >= 0
int power(int base, int n) {
    int i, p;
    p = 1;
    for (i = 1; i \le n; ++i) {
        p = p * base;
    return p;
```

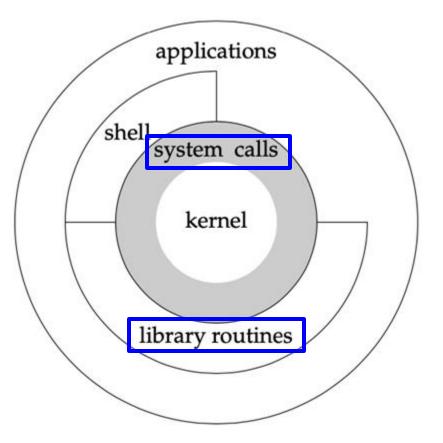

Figure 1.1 Architecture of the UNIX operating system

Diagram from: Advanced Programming in the UNIX Environment, 3rd Ed.

System Calls and Library Functions

- **System call**: entry point directly into the kernel
 - Linux provides ~400 system calls
 - Exposed as regular C functions
- Contrast with: library functions, which do not represent a direct entry point into the kernel
 - o printf() library function invokes the write() system call
 - malloc() library function invokes the sbrk() system call
 - many library functions do not involve system calls, examples:
 - strcpy() copy a string
 - atoi() convert ASCII to integer
- Manual pages:
 - "section 1" for general UNIX commands: man 1 cd (or, equivalently: man cd)
 - o "section 2" for system calls: man 2 sbrk
 - "section 3" for library functions: man 3 printf

Code Style

Overall goals:

- Correctness
- Readability / Maintainability
- Security
- Performance

Many different code style conventions (often specified at the team/company level) Good starting points:

- <u>Linux Kernel Coding Style</u> (a related <u>checkpatch</u> tool)
- CS50 Style Guide
- SEI CERT C Coding Standard (Secure Code)
